# INTRODUCTION

The Infineum Worldwide Winter Diesel Fuel Quality Survey aims to provide the petroleum refining and distribution industry with an overview of the quality of diesel in the marketplace, allowing international trends to be followed. To achieve its purpose, the Survey needs to cover as much of the globe as possible. For the Winter 2002 survey, some 259 samples were collected in 33 countries around the world. The majority of samples were collected during January and February, deep winter months in the northern hemisphere. In southern hemisphere countries, sampling was delayed until later in the year when true winter grade samples could be obtained.

Samples need to be representative of the diesel purchased by the average consumer, so they are purchased from service stations by Infineum colleagues at local area offices. As a general principle, Infineum tries to get one sample that represents the production from each refinery or region in a given country. To minimise the possibility of taking multiple samples from a single refinery, knowledge of local exchanges agreements and the distribution system is used to select where each sample is collected. For the larger diesel consuming countries, this procedure results in samples that represent a reasonable average of the overall quality. However, for smaller countries or specific producers, spot sampling over a short period of time will effectively only provide a snapshot of production quality, with data derived from only one or two samples. This can make it more difficult to evaluate trends with any accuracy.

Contents

# THE TRENDS

Historically, it has been difficult to offer anything other than general observations when diesel survey data have been analysed with a global perspective. Trends have tended to be confined to specific market segments or geographical regions and have usually been lost in the wider picture. In recent years however, there has been a change. Widespread environmental concerns around the globe have aligned thinking on a scale that would not have been considered possible only a few years ago. The main axis of alignment has been sulphur reduction and it is within this context that we are now able to see what can be described as a truly worldwide trend.

## Sulphur Content

Many publications have already addressed both current and future sulphur levels for the major diesel fuel market regions so these will not be dealt with in detail here. In summary these involve a reduction from the current limit of 350mg/kg to 50mg/kg by 1st January 2005 within Europe, and a reduction from the current limit of 500mg/kg to 15mg/kg by 1st June 2006 in the US and Canada.

Numerous sulphur reductions are also planned in countries outside of the large regions already mentioned. For example, Japan introduced 50mg/kg sulphur diesel in metropolitan areas during October 2002 and will expand this nation-wide before midyear 2003.

The specification reductions may appear to be substantial and the time scales short, but in a number of countries they also belie reality. Tax incentives have been applied by a number of European governments that are driving sulphur content reduction ahead of legislation. It is currently the case that; Belgium, Denmark, Finland, Netherlands, Norway, Poland and the UK produce diesel with less than 50mg/kg of sulphur. These are impressive reductions by any standard, but are overshadowed by Sweden, where sulphur levels are already below 10mg/kg, by Germany, where sulphur will be below 10mg/kg by 1st January 2003, and by Italy, where 10mg/kg sulphur diesel became an optional grade during November 2002.

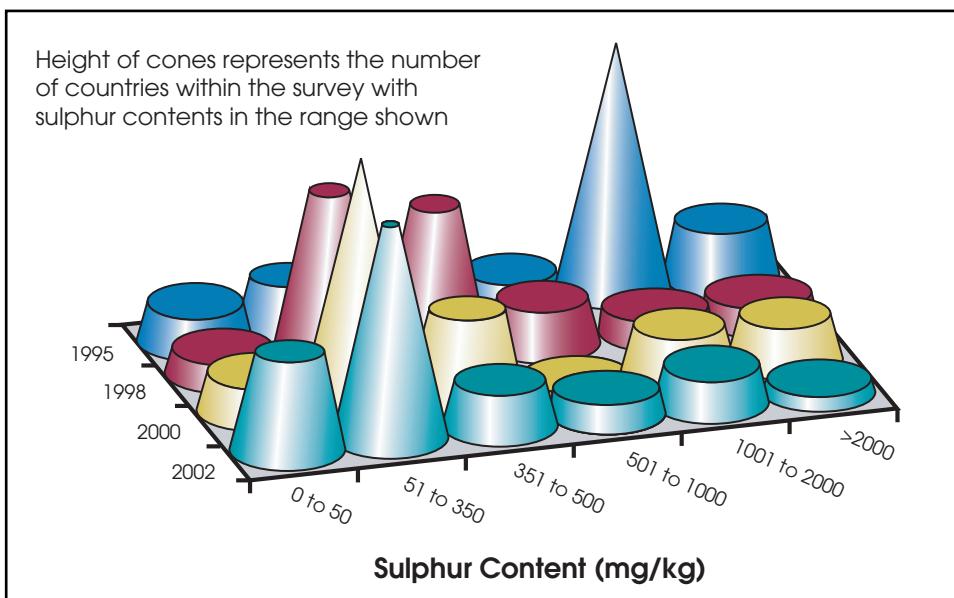

Contents

# THE TRENDS

The sulphur reductions driven by tax incentives are clearly visible in the trend depiction shown here, but these are only one part of a much wider picture.

The survey data show that in 1995 the majority of countries surveyed produced diesels with sulphur contents of between 1000mg/kg and 2000mg/kg. By 1998, the peak had moved to between 50mg/kg and 500mg/kg, and the latest survey shows another step forward - with the majority of production now occurring at between 0mg/kg and 350mg/kg.

## Lubricity

It is now widely accepted that increased desulphurisation has an adverse effect on the lubricating qualities of diesel. This has resulted in the widespread use of lubricity additives and the adoption of lubricity test methods and specifications for quality control. The test method most commonly accepted today is the High Frequency Reciprocating Rig or HFRR. Most specifications that include lubricity performance require that HFRR wear scars are limited to a maximum of 460µm, though it is worth noting that the Worldwide Fuel Charter currently recommends a maximum of 400µm.

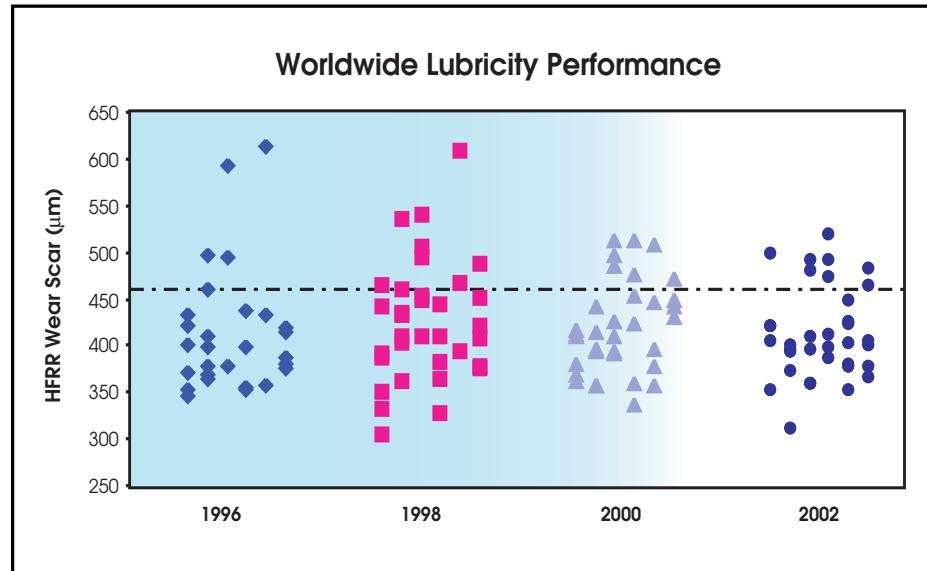

Back

Forward

# THE TRENDS

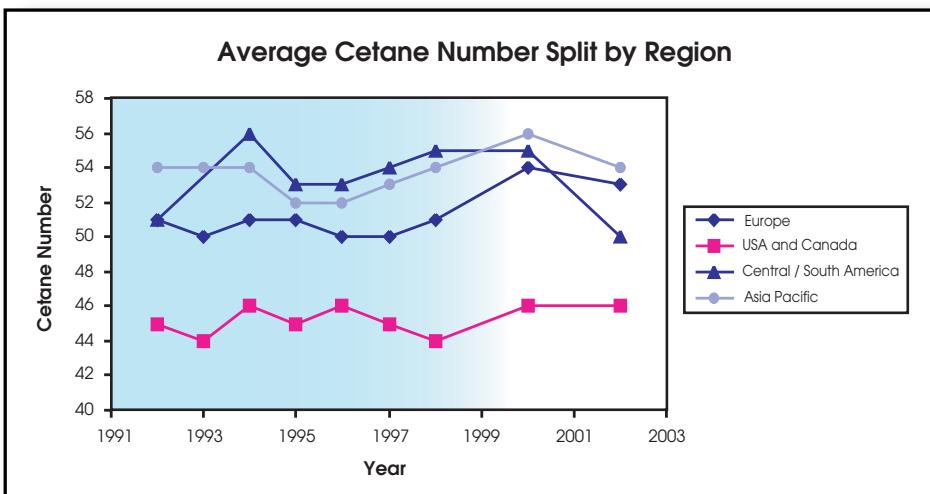

HFRR data generated during the diesel surveys conducted since 1996 show that lubricity standards have been maintained despite the dramatic sulphur reductions that have been recorded for the same period.

## Cetane Number

The latest edition of the Worldwide Fuel Charter continues to advocate high diesel cetane number as a means of reducing vehicle exhaust emissions. For use in regions where advanced emission control requirements exist, fuels are recommended to have cetane numbers of 55 or above. Less stringent levels are recommended for markets with lower level emission control requirements, but the absolute minimum for use in the most basic market is still recommended to be 48.

Diesel survey data collected over the past 10 years do show a trend towards increasing cetane number in most regions, though even today the majority of diesel fuels produced fall short of the Worldwide Fuel Charter recommendations.

Contents

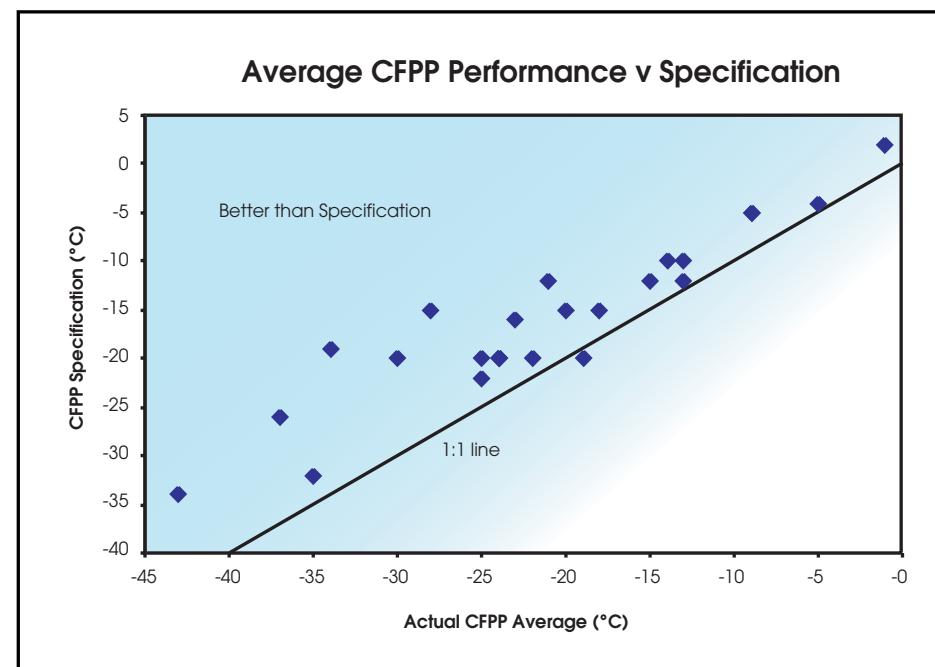

# THE TRENDS

Asia Pacific countries remain at the top of the cetane ladder, while the different approach to cetane in the US and Canada retains this, largely heavy duty market, at the bottom. It should be noted however, that US West Coast diesels do have higher cetane values than indicated by this chart as these fuels need to meet California Air Resources Board cetane requirements. A specification change within Europe in 2000 has now increased cetane numbers in this region to something approaching the levels of those in Asia Pacific. Cetane levels in Central/South America appear somewhat erratic in this analysis, but this is probably more a function of variation of the countries included in the surveys.

## Cold Flow

Cold flow specifications were set in most countries many years ago and have not changed significantly over the past 10 years. It is, therefore, not surprising that trends in cold flow performance are not detected within the survey data. However, this is an important area for refiners and should not be forgotten. In most areas, cold flow performance is now established by test methods designed to protect the most severe vehicles in the field. Cold Filter Plugging Point, or CFPP, is the most widely used of these test methods and has been used to evaluate samples collected during this survey.

This chart compares average measured CFPP values versus specifications for all surveyed countries that use CFPP as the primary cold flow specification. The chart clearly demonstrates that the majority of diesel fuels tested during 2002 either met or exceeded the cold flow specifications imposed.

# TEST METHODS

# TEST METHODS

The majority of testing was carried out at quality accredited laboratories in the USA and UK where the following test methods were used:-

Density	ASTM D 4052
Kinematic Viscosity	ASTM D 445
Sulphur Content	ASTM D 2622
Cetane Number	ASTM D 613
Cetane Index	ASTM D 4737/ASTM D-976
Pour Point	ASTM D 97
Distillation	ASTM D 86
Cloud Point	ASTM D2500
CFPP	IP 309
HFRR	ISO 12156-1
Wax Content	Differential Scanning Calorimetry
LTFT	ASTM D4539

Samples collected in Japan were tested at local laboratories, using the same or similar test methods.

Data on Korean and Chinese diesel was provided directly by the local authorities so information on test methods used is not available.

Contents

# ANALYSIS

The analyses applied to each sample are those we consider will be of most interest to the diesel producers, distributors and consumers. They cover areas of national specification, exchange specification and performance parameters. A degree of standardisation has been applied to enable diesel from all countries to be compared and the data analysed as a single set. Standardisation and space restrictions however, mean that not all national specifications are reported.

For samples collected in the USA, low-temperature flow test (LTFT) results have been reported. These provide an indication of the vehicle performance limit which can be expected in the North American markets.

Wherever possible, industry standard test methods have been applied and in house test methods avoided. This has been done so that the data published here most accurately reflect the results which could or would be generated by organisations within the petroleum industry.

When considering our data, in particular when comparing the various test results with the national specifications, it should be noted that a number of the tests have quite wide reproducibility bands and very little repeat testing has been conducted to determine compliance or otherwise with the specifications.
